Most genetic variants that contribute to disease<sup>1</sup> are challenging to correct efficiently and without excess byproducts<sup>2-5</sup>. Here we describe prime editing, a versatile and precise genome editing method that directly writes new genetic information into a specified DNA site using a catalytically impaired Cas9 endonuclease fused to an engineered reverse transcriptase, programmed with a prime editing guide RNA (pegRNA) that both specifies the target site and encodes the desired edit. We

- All 4 transitions, all 8 transversions
- Insertions (1 to 44 bp)
- Deletions (1 to 80 bp)
- Combinations of above

# Prime Editor

The prime editor complex includes a **Cas9 enzyme**, modified to only nick one strand of DNA, and a **reverse transcriptase enzyme**, which can generate new DNA by copying an RNA template.

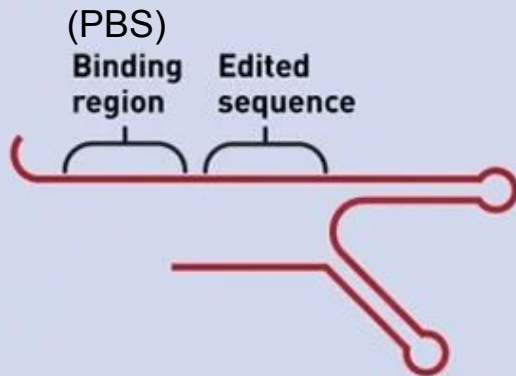

An engineered "**pegRNA**" (prime editing guide RNA) sends the editor to its target, where **Cas9 nicks the DNA**.

# pegRNA

The **pegRNA** has two special components: **a section that binds to the nicked DNA**, preparing the nicked strand to have new DNA letters added, and **a section of RNA letters that encode the desired edit**.

To transfer the edited sequence from the pegRNA to the target DNA, the **reverse transcriptase** reads the **RNA** and attaches the corresponding DNA letters to the end of the **nicked DNA**.

# Prime Editing

An **endonuclease** in the cell naturally excises the **old segment** of DNA and seals the **new letters** into the genome.

Now, the target site is left with **one edited strand and one unedited strand.**

# Prime Editing (cont.)

To resolve the mismatch, favoring the permanent installation of the edited DNA, a **different guide RNA** directs the **prime editor** to nick the unedited strand.

This nick prompts the cell to remake that nicked strand, using the **edited strand** as a template, thus completing the edit.

# First Generation of Prime Editors (PE 1)

- Fused an M-MLV (Moloney murine leukemia virus) RT to the C terminus of Cas9 nickase
- Used different primer binding system (PBS) lengths: 8-15 nt

Could introduce:

- Transversion point mutations (Efficiency: 0.7 to 5.5%)
- Insertions and deletions (Efficiency: 4 to 17%)

# Second Generation of Prime Editor (PE 2)

Improve prime editing efficiency by engineering the RT

- Replaced original M-MLV RT with an engineered one (6 mutations)

Increased efficiency in:

- Point mutations (up to 5.1-fold)
- Insertions, deletions

# Third Generation of Prime Editor (PE 3)

To ensure edit was integrated: use Cas9 nickase to nick the non-edited strand

- Tested a variety of nick locations on non-edited strand
- Optimal: ~50 bp away from the original nick

Increased editing efficiency by 1.5 to 4.2 folds in comparison to PE 2

# Sickle Cell Disease

Caused by an A•T-to-T•A transversion mutation in *HBB* gene

Experiment (Anzalone *et al.* 2019):

- 1) Used PE3 to insert mutation into HEK293T cells with 44% efficiency and 4.8% indels
- 2) Treated cell lines homozygous for the mt *HBB* allele with PE3

Able to get editing efficiencies up to 58% with 1.4% indels

# Tay-Sachs Disease

4-bp insertion  
(TATC) in the  
*HEXA* gene

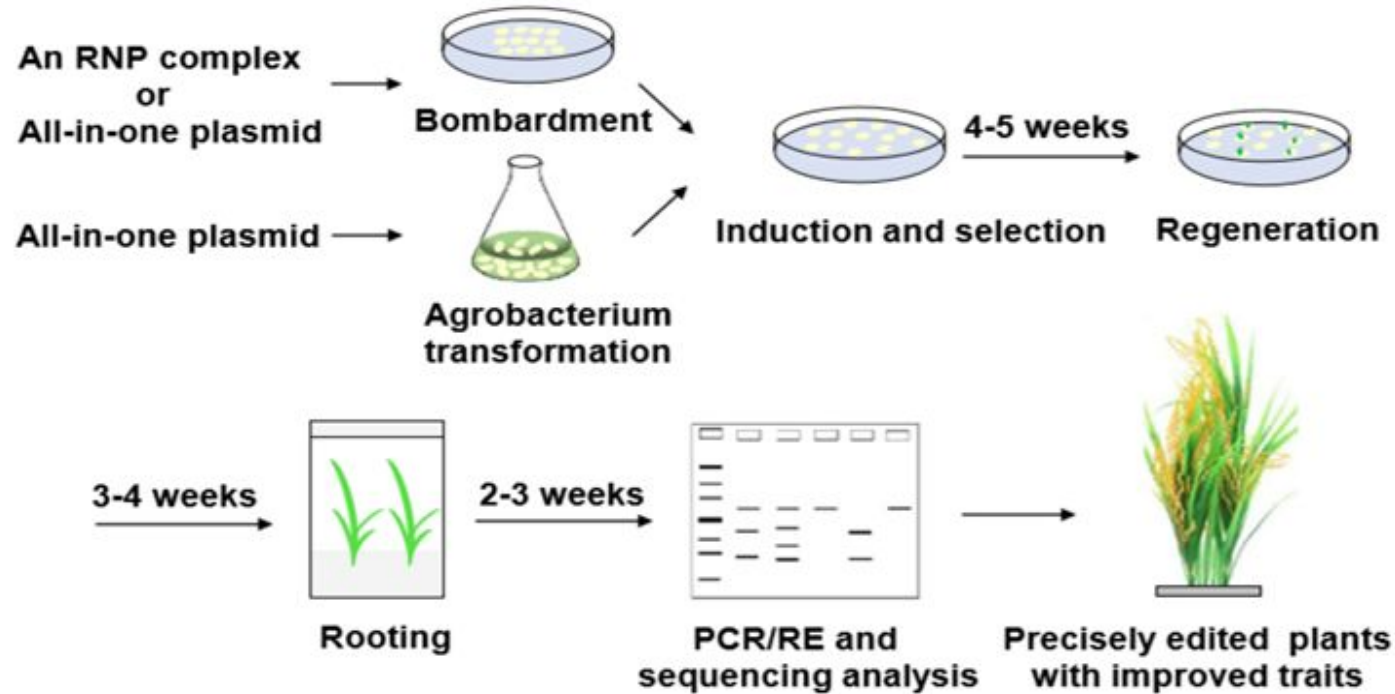

[https://www.osmosis.org/learn/Tay-Sachs\\_disease\\_\(NORD\)](https://www.osmosis.org/learn/Tay-Sachs_disease_(NORD))

Experiment (Anzalone *et al.* 2019):

- 1) Used PE3 to insert 4-bp with 31% efficiency and 0.8% indels
- 2) Homozygous cell lines were used to correct insertion with PE 3

Able to get editing efficiencies up to 33% efficiency and 0.32% indels

# Dual-luciferase reporter system was constructed

# Prime Editing vs. CRISPR-Cas9

<b>Prime editing</b>	<b>CRISPR-Cas9</b>
Nicks only one of the two strands of DNA	Cuts both strands at target site
Targeting apparatus is pegRNA	Targeting apparatus is gRNA
Employs DNA mismatch repair	Relies on non-homologous end joining (NHEJ) or homology dependent repair (HDR)
DNA repair is Error free	NHEJ is Error prone
Length of edits: <100bp	Length of edits: 300-1000bp

## Conclusion

- Can insert DNA sequences with single-nucleotide precision without DSBs
- In principle, can correct about 89% of pathogenic human genetic variants
- Can be used to engineer specific and desired traits in crops
- Precise, lower chance of unwanted edits, easy to use and implement

Prime editing is new tool that can be used to expand the scope of genome editing.
